

Internal Defense Notes
AP Biology **Mrs. Laux**

- **Internal environment of animals provides attractive area for growth of bacteria, viruses, fungi**
- **Harm via:**
 1. **destruction of cells**
 2. **production of toxic chemicals**
- **To protect against foreign invaders, humans possess 3 levels of defense**

I. Nonspecific First Line of Defense

A. Basics:

1. **physical barriers that prevent entrance of pathogens (skin, mucous membranes)**
2. **not specialized**
 - a. **humans→oil and sweat glands acidify skin (pH~3-5) which discourages microbial growth**
 - b. **saliva, tears, mucous secretions**
 - i. **wash away invading microbes**
 - ii. **contain antimicrobial proteins (ex: lysozyme) that break down cell walls of many gram (+) bacteria**
 - c. **mucous membrane-cilia sweep invaders out of trachea, bronchi**
 - d. **gastric juice of stomach (pH 1.5 to 2.5) kills most bacteria**
 - e. **symbiotic bacteria in digestive tract and vagina outcompete other organisms that could cause damage (ex: yeast infection)**

II. Second Line of Defense

→nonspecific mechanism

A. Amoeboid WBCs→phagocytosis of microbes that pass 1st line

1. **Neutrophils (kamikaze cells)**
 - a. **become phagocytic in infected tissue**
 - b. **attracted by chemical signals**
 - c. **only live a few days and destroy self while destroying pathogens**
2. **Monocytes→Macrophages**
 - a. **large phagocytic cells**
 - b. **found in interstitial fluid or permanently in organs and connective tissue**
 - c. **phagocytize pathogens, other foreign cells, neutrophils with pathogens**
3. **Eosinophils**
 - a. **limited phagocytic activity**
 - b. **contain destructive enzymes; discharged against outer covering of invading pathogens**
 - c. **used mainly against parasitic worms (tapeworms)**
4. **Natural killer cells (NK cells)**
 - a. **destroy body's own cells when:**
 - i. **cells are infected by viruses**

Internal Defense Notes
AP Biology **Mrs. Laux**

- ii. abnormal body cells, such as tumors
- b. do not phagocytize cells, attack cell membranes, which cause cells to lyse
- c. part of both specific and nonspecific lines of defense

B. Antimicrobial Proteins

1. either directly attack pathogens or interrupt their reproduction
2. most important: complement
 - a. 20 proteins in plasma, ICF
 - b. inactive until body is exposed to an antigen
 - c. non specific because will react against any foreign antigen
 - d. functions:
 - i. cause lysis of pathogens by poking holes in cell membrane
 - ii. coat pathogens so that phagocytes will engulf
 - iii. attract WBCs to area of infection by releasing attracting chemicals
 - iv. increase inflammation by stimulating release of histamine (dilates and makes capillaries more permeable)

C. Cytokines

1. type of cytokines
 - a. regulatory proteins
 - b. important in signaling immune response
 - c. how immune cells communicate with one another
2. Interferons
 - a. chemicals produced by virus-infected cells (like macrophage or some tissue cells)
 - b. activate immune response to come and kill cell with virus inside
3. Interleukins
 - a. cytokines secreted mainly by macrophages and lymphocytes
 - b. activate different cells of immune system
 - c. ex: lymphocytes are “tagging” destroying pathogens-will attract macrophages to come and clean up the “mess”
 - d. IL-1, IL-2-numbered in order of discovery

D. Inflammatory Response

1. occurs when there is damage to tissue or entry of pathogens
2. cut in skin, bacteria enters-series of events occur:
 - a. Basophils and mast cells (connective tissue cells with granules) secrete histamine→causes:
 - i. vasodilation of blood vessels surrounding damaged area
 - a. increases blood supply for increased # WBCs, increased pressure pushes WBCs to tissue
 - b. increases % nutrients to supply cells and WBCs

- c. causes redness, increased temperature, and swelling (edema)
 - d. increased temperature favorable for WBCs, unfavorable for pathogens
 - ii. capillaries become more permeable
 - a. Antibodies pass from blood to infected area
 - b. causes edema and pain
 - b. phagocytes migrate because attracted by complement
 - i. neutrophils arrive first, then macrophages
 - a. neutrophils kill pathogens and then die
 - b. macrophages → destroy pathogen and clean up remains of damaged tissue cells and dead neutrophils
 - c. dead cells and fluid from capillaries may accumulate as pus
 - ii. phagocytes release interleukin-1: cause fever
- 3. Widespread (systemic)-inflammatory response
 - a. may occur as a result of severe infections (ex: meningitis, appendicitis)
 - b. may be a large increase in # of WBCs within hours (white count)
 - c. system wide inflammatory response → fevers develop
 - too high, dangerous
 - moderate: facilitate phagocytosis, increase tissue repair

III. Third Line of Defense → Immune Response

A. Definition-Immune system characteristics

1. Specificity → system's ability to recognize and eliminate particular microorganisms and foreign molecules

a. antigen

- i. any molecule, usually a protein or polysaccharide, that may be identified as foreign and will elicit an immune response
- ii. ex: toxin (insect bite, bacteria) protein coat of a virus-molecule unique to a cell membrane of bacteria, worms, pollen, protozoa, ...
- iii. each antigen has a unique molecular shape and stimulates production of a particular antibody that defends against that antigen

b. antibody (Ab) or immunoglobulin (Ig)

- i. antigen-binding protein that acts as an effector for immune response
- ii. secreted by B-lymphocytes

Internal Defense Notes
AP Biology **Mrs. Laux**

iii. structure: 4 polypeptide chains-(2 light, 2 heavy); C-region-amino acid chain is constant within class; V-region-unique to antibody for a particular antigen

2. Diversity

- a. immune system has ability to respond to numerous kinds of invaders
- b. each invader is recognized by a particular antibody(ies)

3. Memory

- a. ability to recognize previously encountered infections
- b. body reacts quickly and efficiently to repeat infections
- c. acquired immunity
- d. ex: chicken pox

4. Self-nonsel self recognition

- a. body can distinguish between itself and foreign antigens
- b. body uses major histocompatibility complex (MHC) to distinguish between self and nonself cells
 - i. collection of glycoproteins (proteins and carbohydrates) that exist on cell membrane
 - ii. biochemical fingerprint-no 2 people, except identical twins, have identical MHCs
 - iii. immune systems react when they come in contact with MHC of another organism
 - iv. more related-more MHC proteins in common
 - v. 2 important classes:
 - a. MHC class I antigens are found on most nucleated cells
 - b. MHC class II antigens are found on B-cells, macrophages; allow these cells to become antigen presenting cells (APC)-macrophages-once engulf pathogen will degrade within itself, then bring protein part to its MHC; has become an APC-will travel to lymph nodes to meet up with lymphites and initiate specific response

B. Active vs. Passive Immunity

1. Active Immunity

- a. immunity acquired after recovery from infectious disease
- b. depends on response of own immune system→responds, fights, and remembers
- c. may be acquired:
 - i. naturally→from infection
 - ii. artificially→from vaccine
 - a. may be: bacterial toxin, dead pathogen, weakened pathogen
 - b. can no longer cause disease, but do stimulate immune response
- d. long-term response

2. Passive Immunity

- a. when immunity is transferred from one person to another via transfer of antibodies
- b. temporary-few weeks or months
- c. natural: pregnant mother → smaller antibodies to fetus, nursing
- d. artificial → injecting person with antibodies from another person or animal when initial infection would kill the person
 - i. ex: rabies, tetanus, snake venom

C. Cells of the Immune System

→ primarily: lymphocytes:

1. B cells → antibody-mediated immunity

- a. originate and mature in bone marrow
- b. cell membrane is characterized by antibodies (specialized antigen receptors)
- c. differentiate into plasma, memory cells

2. T-cells → cell mediated immunity:

- a. produced in bone marrow, mature in thymus
- b. no antibodies
- c. differentiate: T_H , T_C , memory cells (different from B cell memory cells)

3. mature B and T cells are concentrated in lymph nodes, spleen, and other lymphatic organs → most likely to make contact with antigens

4. both have antigen receptors:

- a. B cells → antibodies
- b. T cells → receptors embedded in membrane

IV. Antibody-Mediated (Humoral) Response

A. B-cells → antibodies (Ig)

→ structure associated with function

1. y-shaped molecule with 4 polypeptide chains:

- 2 light chains
- 2 heavy chains

a. all 4 chains have constant regions that vary little in amino acid sequence from one Ig to next

b. V-region → tips

- i. extreme variation
- ii. antigen-binding sites
- iii. amino acid sequences enable antibody to recognize and “fit” into antigen

2. 5 classes of antibodies based on composition of constant regions:

a. IgM → pentamer (5 Ys)

- i. circulating antibodies which appear in response to initial exposure to an antigen (primary response)
- ii. too large to leave blood and lymph vessels

b. IgG → monomer

- i. most abundant in blood

Internal Defense Notes
AP Biology **Mrs. Laux**

- ii. small → diffuses through placenta
- iii. also → bacteria, virus, fungi, toxins
- iv. chief → secondary immune response (after initial)

c. IgA → dimer

- i. prevents attachment of pathogens to epithelial surfaces
- ii. found in saliva, tears, sweat

d. IgD → monomer

- i. rare
- ii. found on surface of B-cells

e. IgE → monomer

- i. stem regions attach to basophils
- ii. stimulate histamine response when triggered by allergen

3. How antibodies work:

- a. do not directly destroy pathogen
- b. binds to antigen-forming an antigen-antibody complex, which tags invaders for destruction by one mechanism:
 - i. antibody-antigen complex may inactivate pathogen or its toxin
 - ii. clumping of cells for easier destruction by the phagocytes
 - iii. activation of complement → lyses cells

B. Humoral Reaction (medieval times: humor = body fluids)

1. B-cells are circulating in blood and lymph

- a. each carries specific antibodies
- b. antibodies were created during embryonic development, just waiting for exposure to antigen
- c. B cells are primary mode of bacterial infection

2. response begins when antigen binds to antibody on cell membrane of a B-cell

- a. be presented by APC to T_H
- b. usually activated by T_H cell

3. once B-cell is activated, B cells begin to proliferate (divide and differentiate) into two types of cells:

a. plasma cells

- i. release and secrete antibodies
- ii. antibodies will circulate in blood and lymph binding to antigens
- iii. large areas of rough ER synthesize antibodies

b. memory cells

- i. long-lived B cells that do not release their antibodies at initial infection
- ii. circulate the body and respond to any subsequent infection by same antigen
- iii. provides immunity after first occurrence of disease

- c. theory of clonal selection**
 - i. antigen “selects” which lymphocytes will divide to form clones**
 - ii. permits body to make large quantities of antibodies only when needed**

B cells: Humoral Response

B-cell in blood/lymph is activated

B cell

plasma cells (millions)

**activate phagocytes
complement; inactivate toxins**

memory cells

**ready for secondary
infection**

V. Cell-Mediated Response

A. T cells

- 1. antigen receptors are not antibodies, but are recognition sites for molecules displayed by nonself cells**
- 2. self and non-self recognition:**
 - a. MHC markers are used to distinguish nonself**
 - b. APC cells display foreign antigens to initiate cell-mediated response**
 - c. cancer cells, tissue cells, and others are recognized as nonself by T cells**
- 3. Types (produced by clonal selection)**
 - a. cytotoxic T cells (T_C cells)**
 - i. killer T cells**
 - ii. recognize and destroy nonself cells by puncturing them and causing them to lyse (perforin)**
 - b. Helper T cells (T_H cells)**
 - i. stimulate proliferation of B and T_C cells upon recognition of nonself cells**
 - ii. important in both humoral and cell-mediated immunity**
- 4. Activation of T cells:**
 - a. respond to antigens on body’s own cells**

Internal Defense Notes
AP Biology Mrs. Laux

b. cannot detect free antigens in body fluids (humoral response)

c. process:

Macrophage (engulfed pathogen)

Infected cell

Becomes APC by displaying MHC nonself markers (pieces of pathogen)

↓
recognition of nonself cells stimulates differentiation of T cells

T_H cells

↓ **bind to nonself marker**
release interleukins

↓
proliferation of T_H cells

↓
release more interleukins

↓
more T_H (positive feedback)

↓
activates B cells

↓
humoral response

↓
antibodies kill other free pathogens in blood and lymph

activates T_C cells

↓
cell-mediated response

↓
binds to antigen displaying nonself markers

↓
secretes perforin

↓
cell lyses

5. T_C cells destroy:

a. macrophages with pathogen

b. cells infected with virus

Internal Defense Notes
AP Biology **Mrs. Laux**

- c. foreign tissue cells**
 - ex: organ transplants**
- d. cancer cells**
 - i. periodically develop in body**
 - ii. possess markers not found in normal cells**
 - iii. TC recognizes as nonself**
 - iv. cancer cells develop in individuals with defective or declining immune systems**
